

# Linking Phenotypic Models and Genotypic Data

---

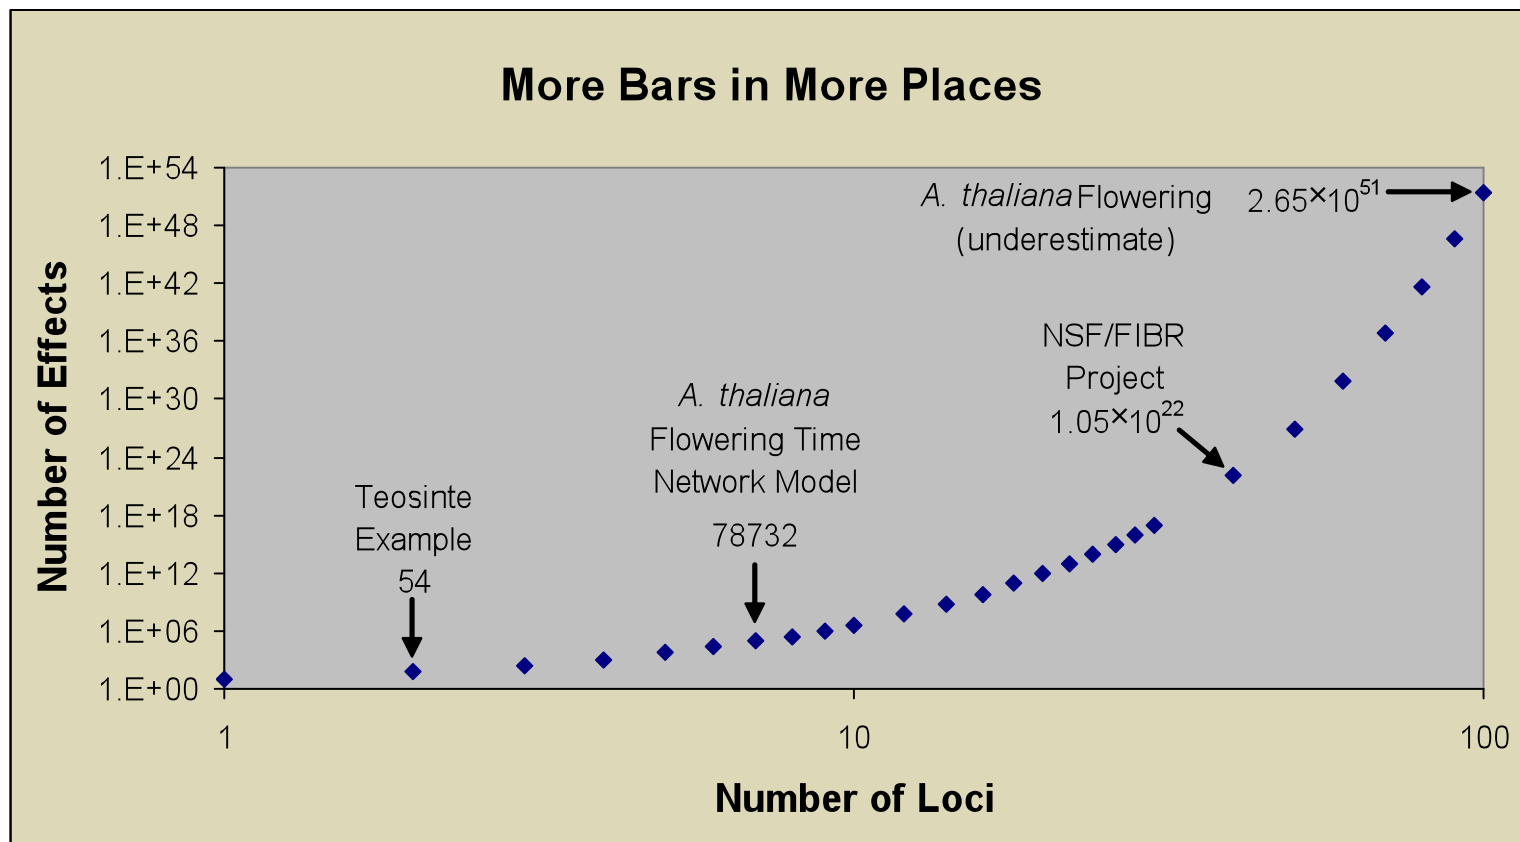

# Four modeling approaches (I)

---

- General linear models that relate phenotypes to genetic markers
  - Used to find markers that may be close to genes that control traits – i.e. does not require prior knowledge of relevant loci
  - Once mapped, markers can be used to predict phenotypes for novel genotypes not used in analysis
  - GLMs are not mathematically efficient at representing  $G \times E$  or  $G \times G$  interactions
  
- Ecophysiological crop models which relate phenotypes to genotypes by fitting crop coefficients to different cultivars
  - Can predict phenotypes in novel environments but cannot predict behaviors of genotypes not fit
  - Efficient representation of  $G \times E$  interactions

# Representing networks as GLMs

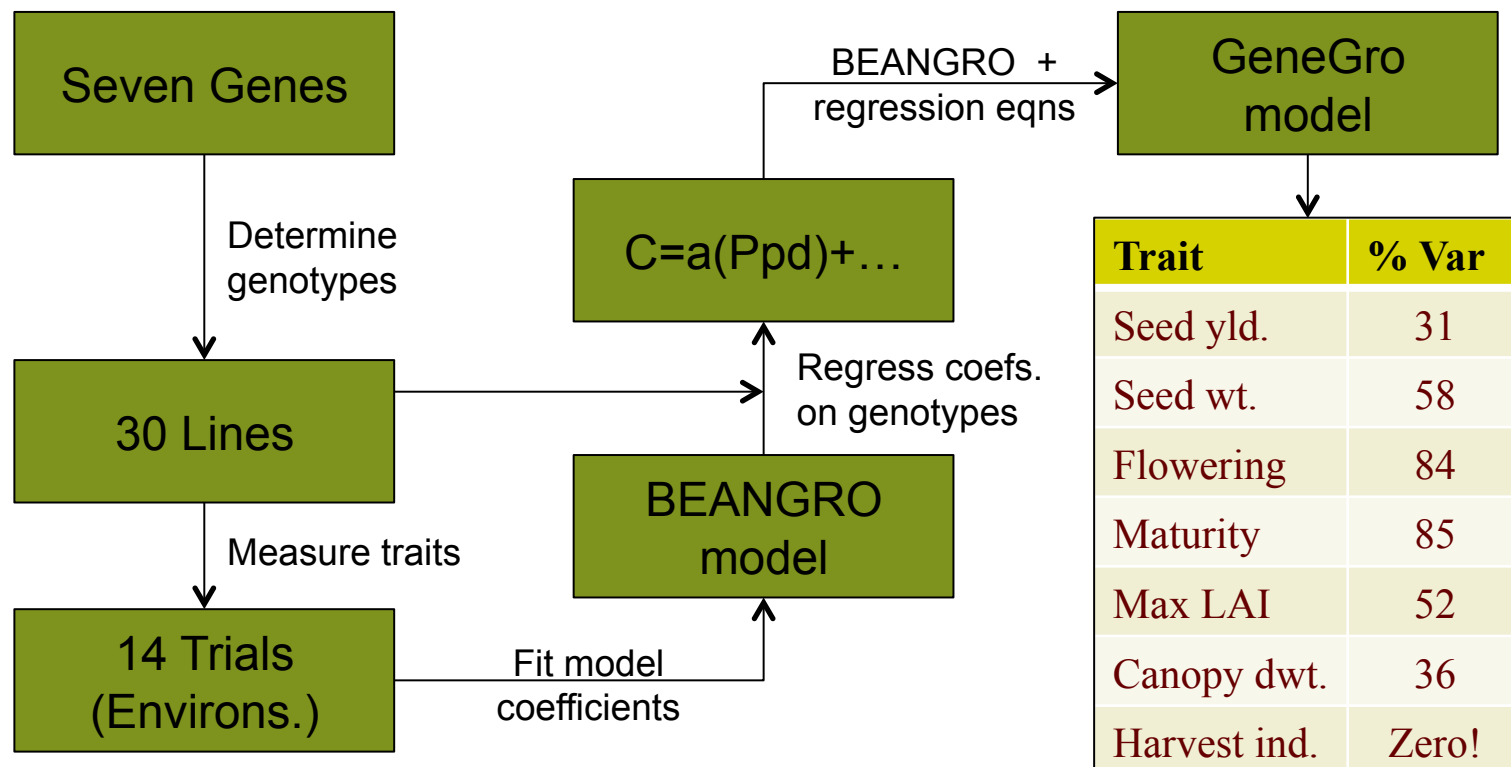

# Four modeling approaches (II)

---

- Ecophysiological crop models whose coefficients are regressed on “candidate alleles”
  - Efficient representation of  $G \times E$  and  $G \times G$  interactions
  - Can make predictions for novel environments and novel genotypes
  - Require relevant loci and alleles to be known ahead of time
- Ecophysiological models whose coefficients are mapped to genetic markers
  - Can be used to find regions (“QTL”) that bracket potentially relevant genes
  - Can predict outcomes for new genotypes in new environments
  - Do not require prior knowledge of relevant genes
  - Efficient representation of interactions

G2P model  
extender tool

Genetic candidates

QTL

Association mapping

$$\theta = \mu + p_1 (Mk_1) + p_2 (Mk_2)(Mk_3) \dots$$

# Example applications

---

- Given a gene network (G2P) model based on a few lab strains, expand it to a large number of genotypes
- Given a ecophysiological model, convert it to a G2P model by linking to candidate genes &/o QTL (incl. *de novo* detection of the latter)
- For any type of model, check for genotypic or environmental dependencies of putative constants that would signal model incompleteness or inadequacy

# A parametric correspondence principle

Polymorphic locus

Alleles:  $A_1 \dots A_n$

Phenotypes:  $Y_1 \dots Y_n$

Model

Some numerical parameter

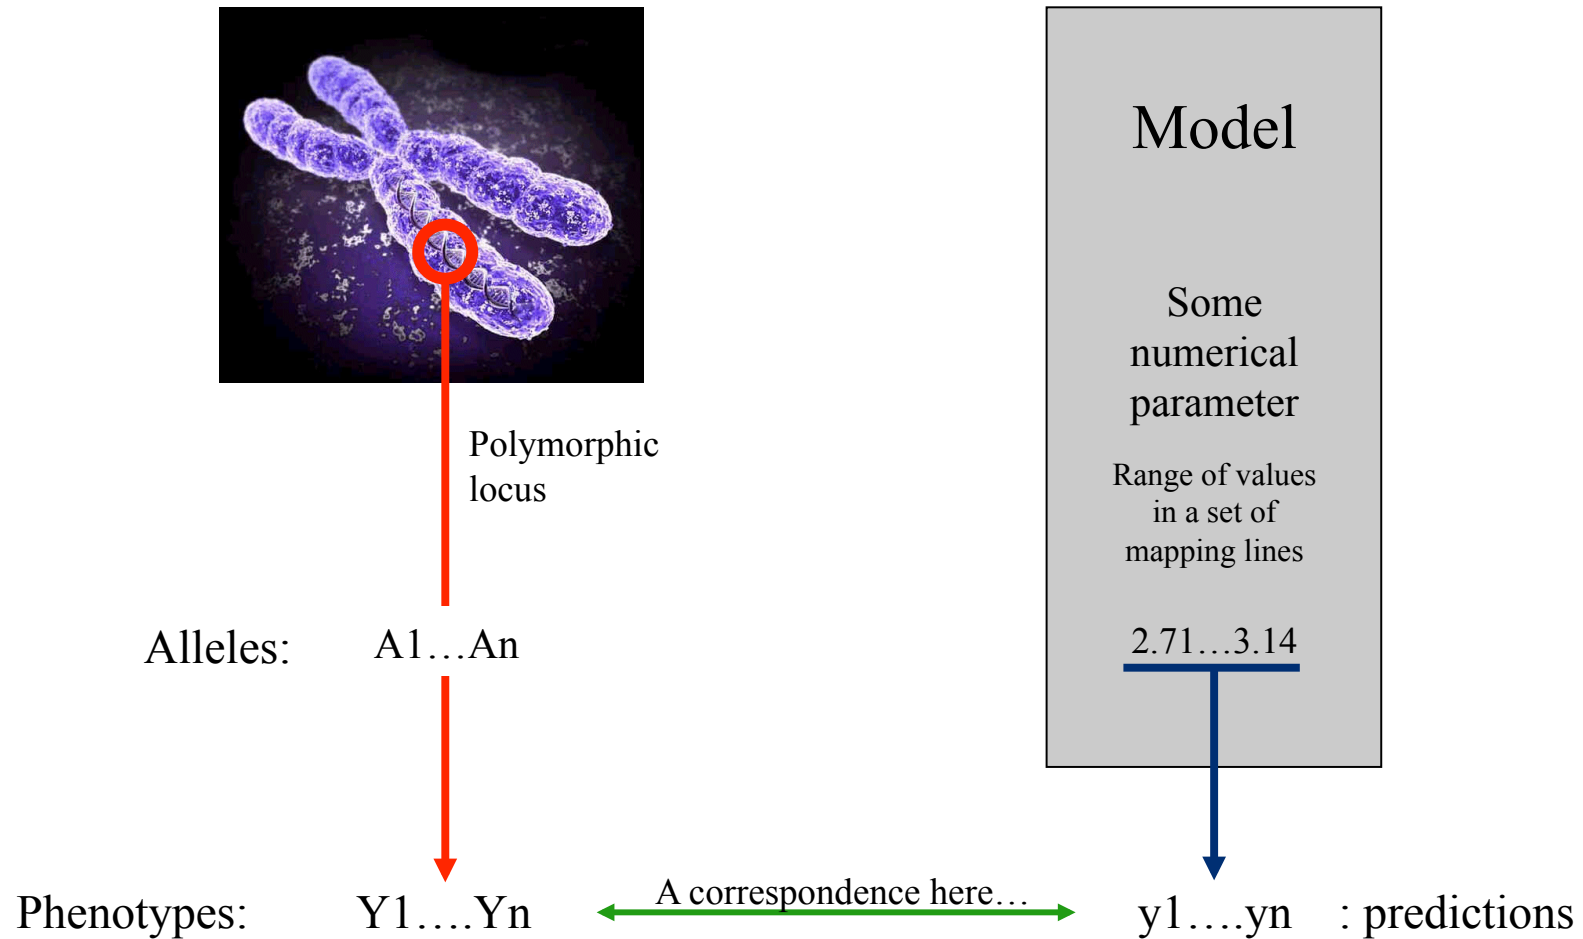

Range of values in a set of mapping lines

$$\frac{dmSOC1}{dt} = (-\beta \cdot mSOC1 + rpSOC1 \cdot (1 + rtSOC1 \cdot mFCA) \cdot (1 + rcSOC1 \cdot mCO \cdot LIGHT) (1 + rySOC1 \cdot CRY2 \cdot LIGHT)) \cdot TEMP$$

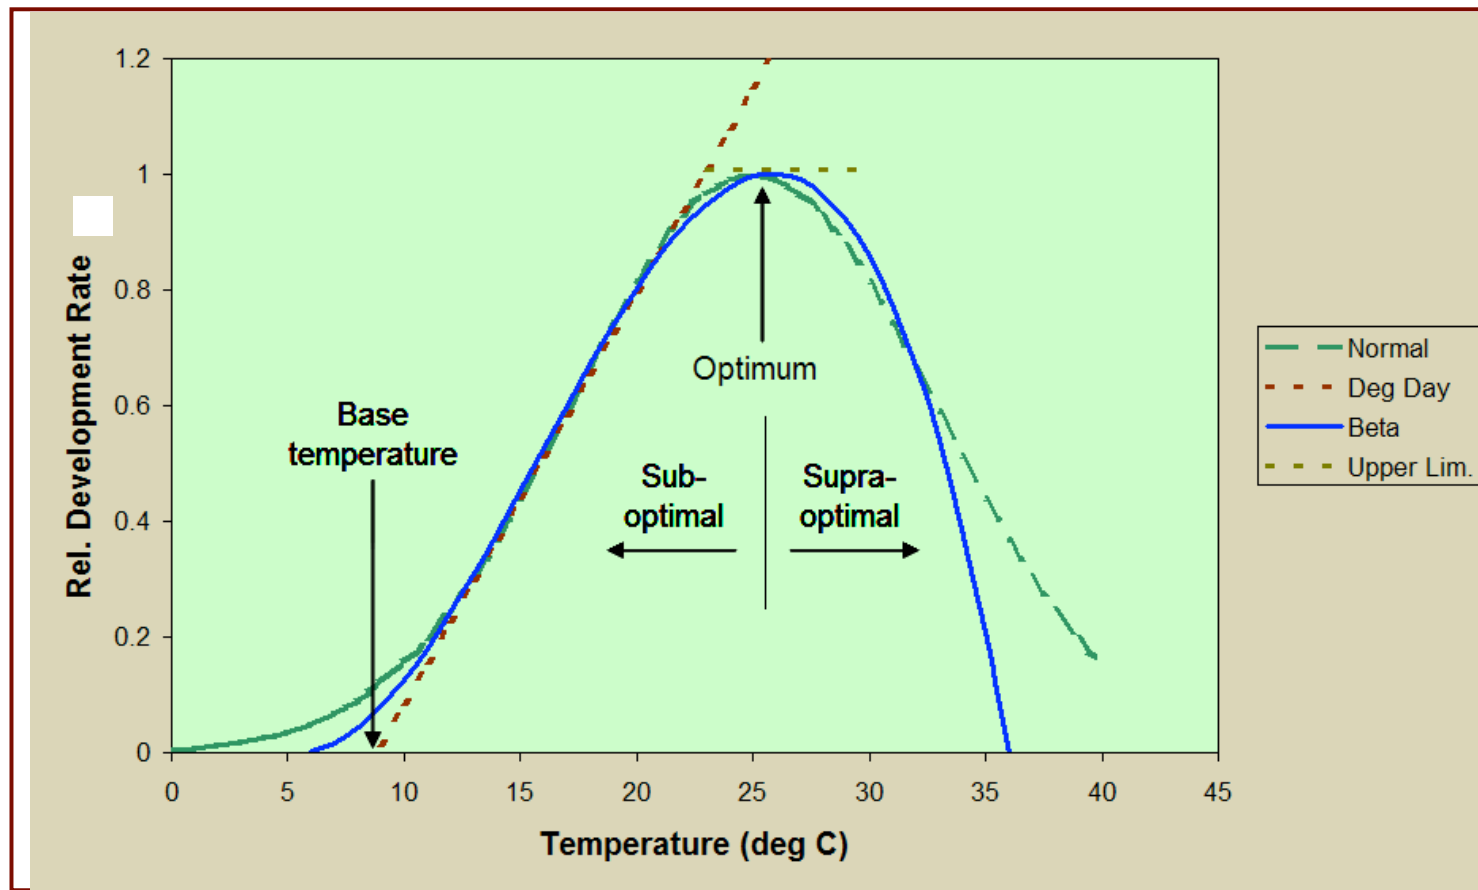

$$\frac{dmLFY}{dt} = -mLFY + 1.0 / (1 + \exp(-rpLFY \cdot mSOC1 - biasLFY))$$

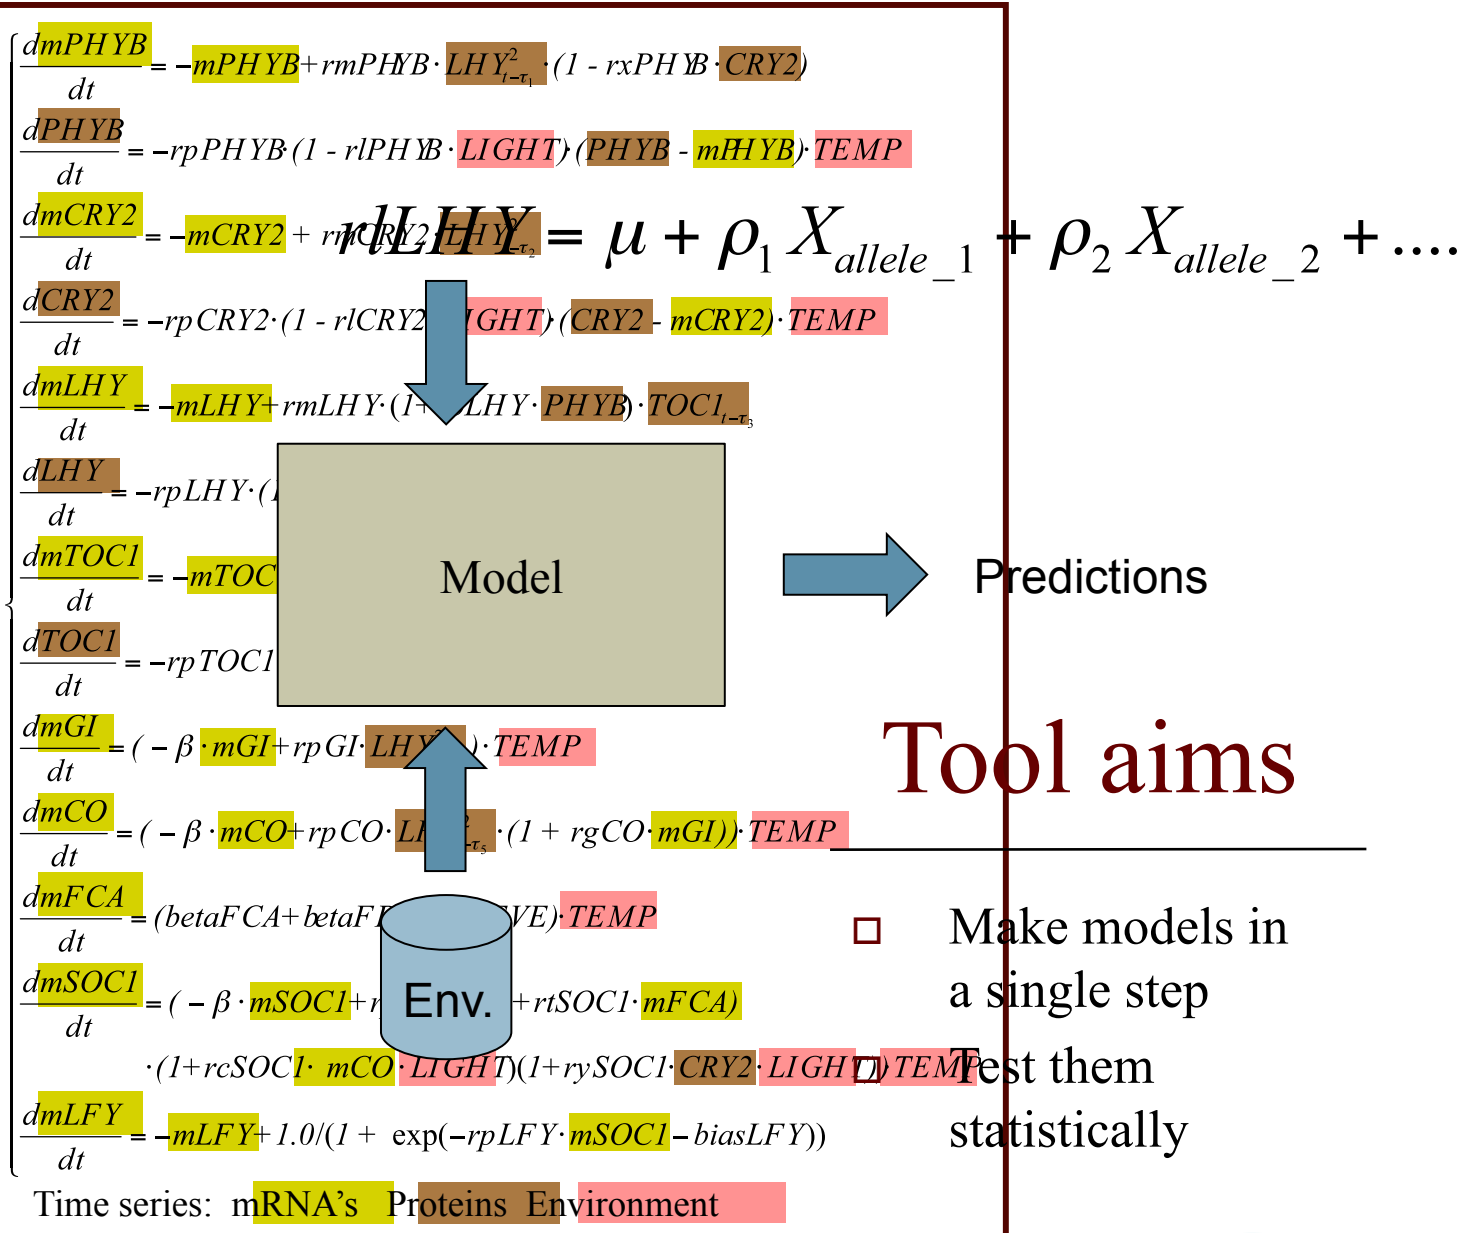

Time series: mRNA's Proteins Environment

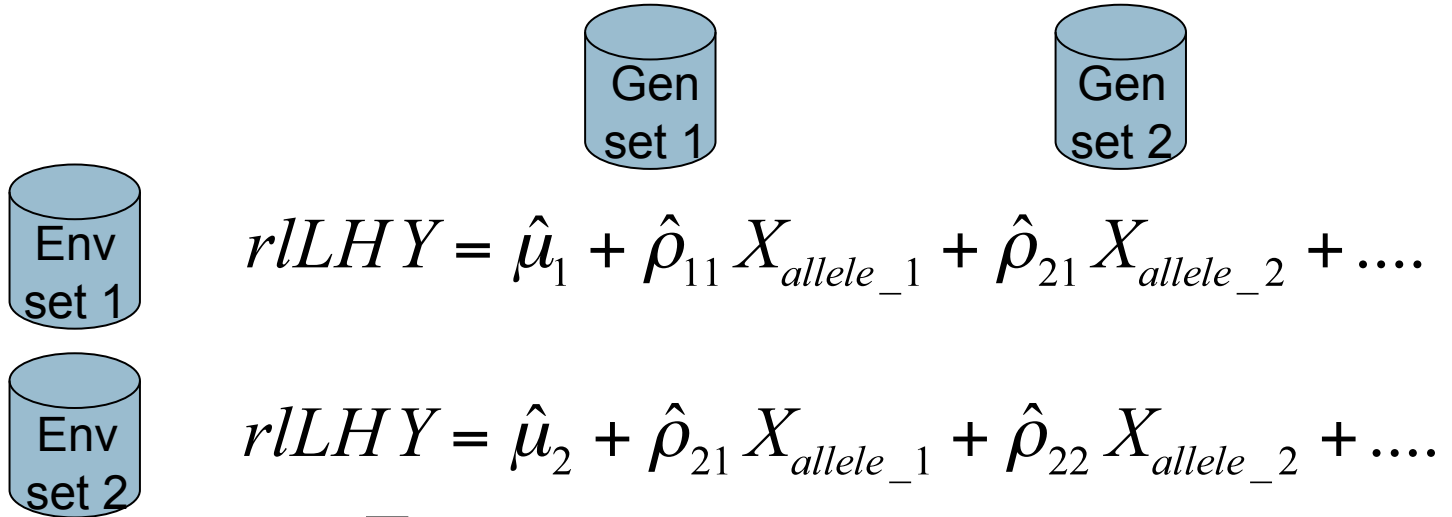

# Where's the linearity?

- Within networks
  - Epistasis is totally trivial
  - Dominance is easy to explain
  - But additivity is a major mystery that requires
    - Linearity &
    - Is readily disrupted in transduction cascades

# Quasi-linear regimes

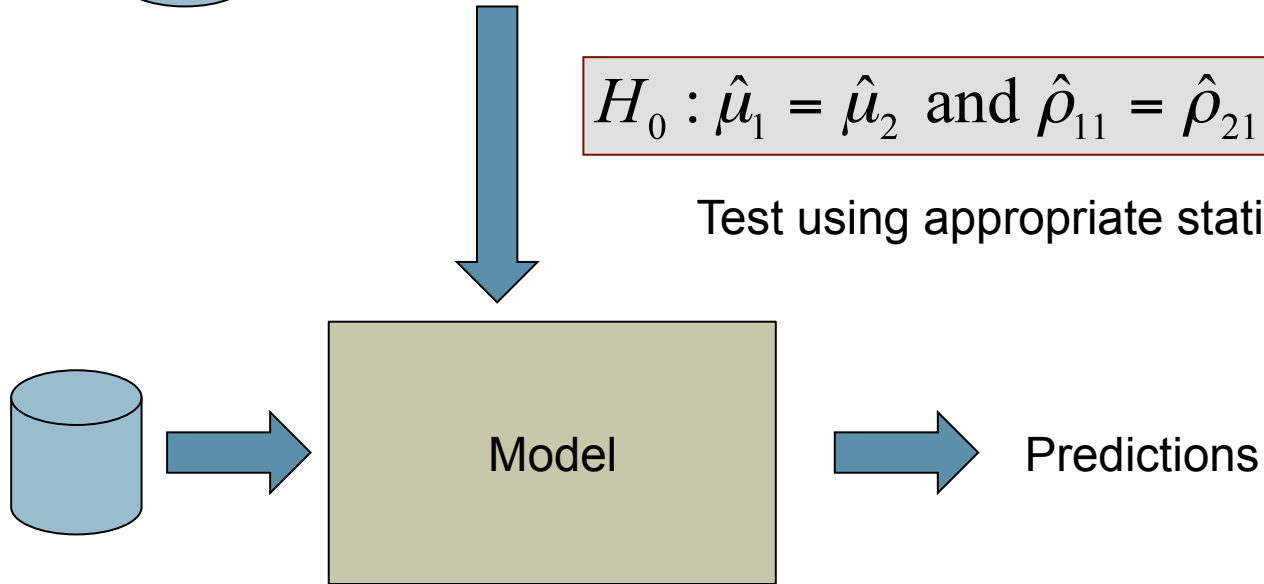

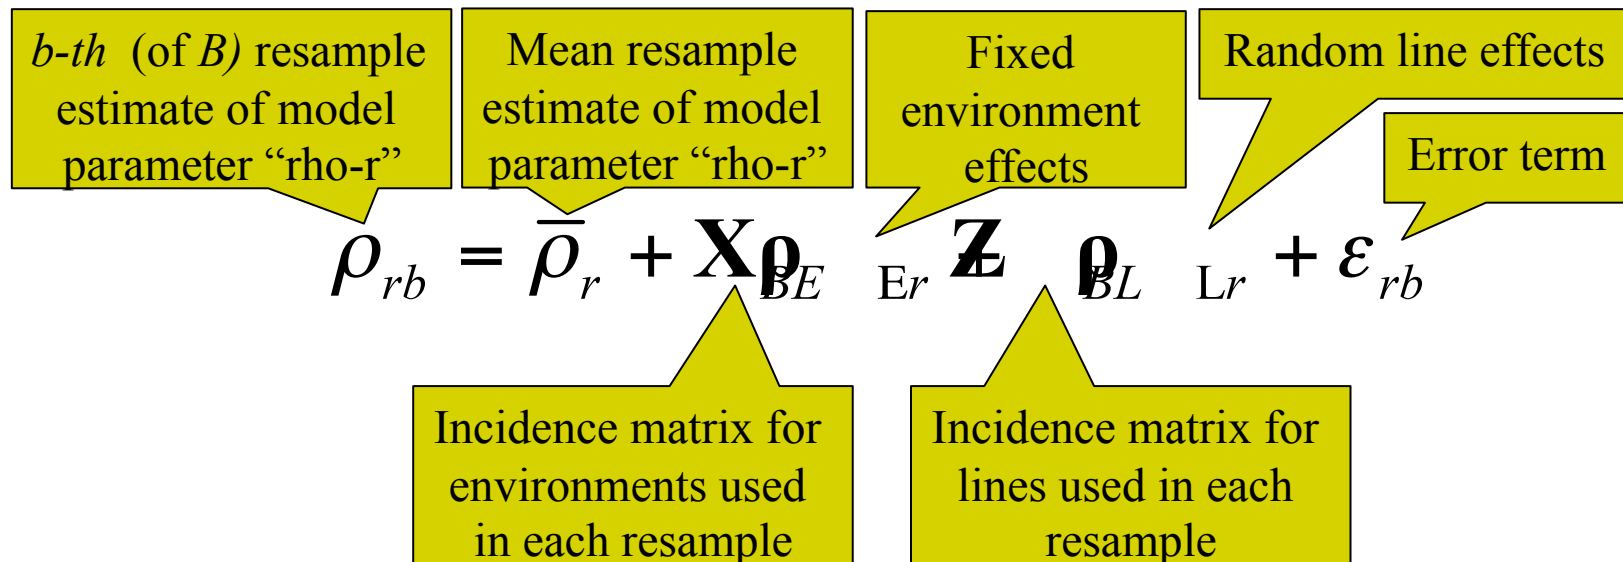

$H_0 : \hat{\mu}_1 = \hat{\mu}_2 \text{ and } \hat{\rho}_{11} = \hat{\rho}_{21} \text{ and } \hat{\rho}_{21} = \hat{\rho}_{22}$

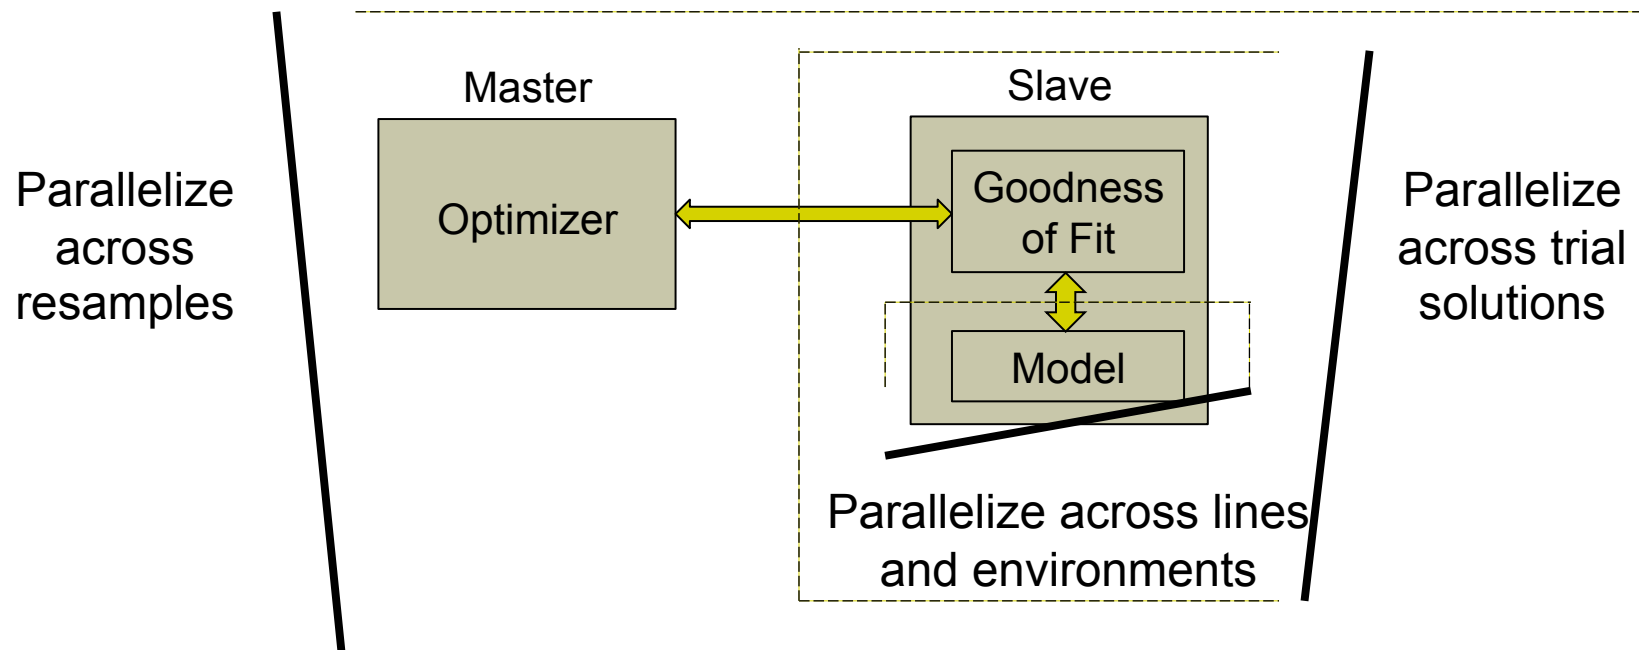

Test using appropriate statistical model
